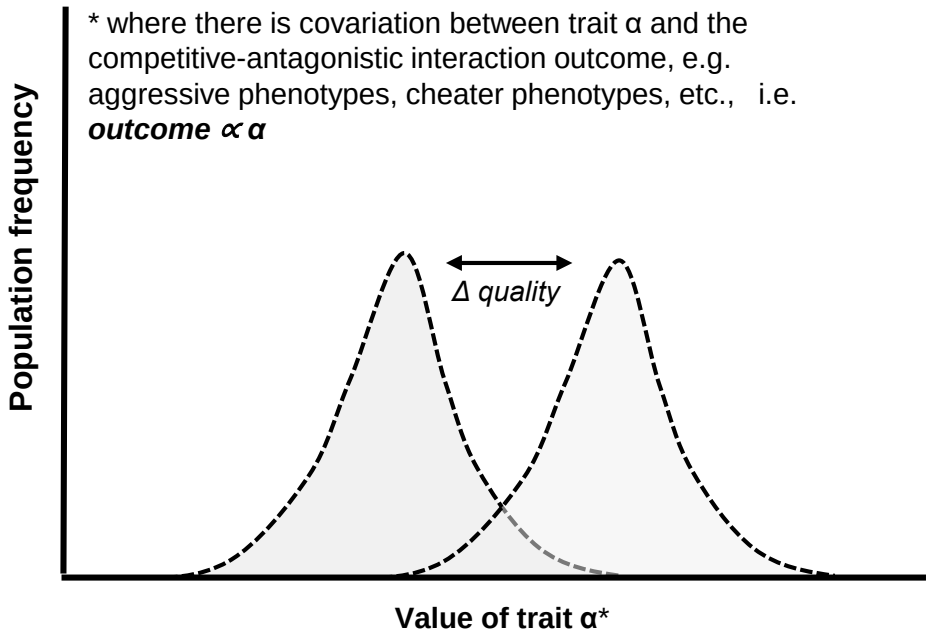
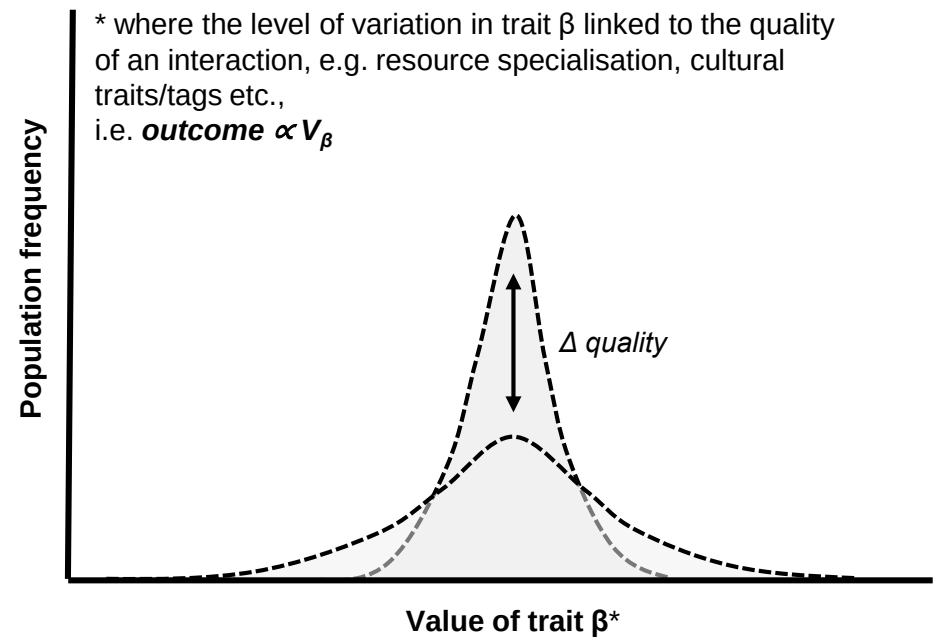
A. *Trait frequency effects*, i.e. within-population changes in the composition of traits linked to cooperation-antagonism, e.g. due to selective or genetic drift effects, or phenotypic plasticity.



B. *Systemic variance effects*, i.e. the level of trait variation within a population is linked to cooperation/antagonism, where greater ITV within a population can be associated with either more cooperative or more antagonistic outcomes.



C. Linking changes in trait variance or composition with outcome shifts along a general continuum. Changes in trait variance may; **(i)** directly produce outcome variation, e.g. by influencing the identify of interaction partners and altering their fitness payoffs; or, **(ii)** produce changes in the composition of cooperation-antagonism linked traits in a population, e.g. by inducing behavioural plasticity (i.e. *systemic variance effects*). Changes in the composition of cooperation-antagonism linked traits then directly lead to outcome variation (i.e. *trait frequency effects*)
